Stylesheet Version 1.0

DISTRIBUTED FILE SYSTEM USING SCATTER-GATHER

Background of Invention

- [0001] It has become conventional to organize personal computer workstations into Local Area Networks or LANs. File sharing from system to system within a LAN is conventionally done in one of two ways. Either there is peer-to-peer sharing established by operating system settings on workstations which are to enable such sharing or there is a file server connected to the LAN which provides storage capability accessible to all, or an identified number, of the systems connected to the LAN.
- [0002] Notwithstanding this conventional practice, it is also conventional for individual systems connected to a LAN to have storage capability which may be underutilized by the workstation operator. Particularly as the data storing capacity of hard drives has risen dramatically in recent times, the storage requirements of an operating system and most application programs and stored data in a personal computer workstation are significantly less than the capability provided. Thus, within a LAN, there will likely be significant storage capability which is available for other use should the systems and network accommodate such use.

Summary of Invention

- [0003] The present invention contemplates that storage capability otherwise going underutilized in a LAN be made available for sharing among workstations connected to the LAN. In realizing this purpose of the present invention, systems connected to a LAN are surveyed for storage capability potentially available for sharing, a weighting function is derived for each system which is indicative of shared system storage capability, and data files to be stored are scattered among and gathered from the connected systems.

Brief Description of Drawings

- [0004] Some of the purposes of the invention having been stated, others will appear as the description proceeds, when taken in connection with the accompanying drawings, in which:
 - [0005] Figure 1 is a representation of a LAN having a number of computer systems connected thereto;
 - [0006] Figure 2 is a schematic representation of a scattering file storage process;
 - [0007] Figure 3 is a schematic representation of a gathering file retrieval process; and
 - [0008] Figure 4 is a representation of a computer readable medium on which program instructions are stored accessibly to a computer system.

Detailed Description

- [0009] While the present invention will be described more fully hereinafter with reference to the accompanying drawings, in which a preferred embodiment of the present invention is shown, it is to be understood at the outset of the description which follows that persons of skill in the appropriate arts may modify the invention here described while still achieving the favorable results of the invention. Accordingly, the description which follows is to be understood as being a broad, teaching disclosure directed to persons of skill in the appropriate arts, and not as limiting upon the present invention.
- [0010] Briefly stated, the present invention contemplates a method of sharing the storage capabilities of a plurality of computer system workstations connected together into a LAN which includes a step of surveying a plurality of computer systems associated one to another through a local area network and determining the free file storage capability of each surveyed system. For each surveyed system, a weighting function is determined based on available storage capacity, network connectivity, and system resources of the respective system. The weighting function, which may here be represented as $w(x)$ with x representing the particular system to which the function is assigned, is indicative of the capability of a given system to cooperate in scatter/gather file sharing as here proposed. Some systems within a LAN may have

significant capabilities, while others may have limited or lesser capabilities. The present invention contemplates that such differences will be taken into account in file storage processes.

- [0011] The systems of the present invention will respond to instruction at one of the plurality of systems to store a data file by dividing the data file to be stored into a plurality of portions to be scattered among the plurality of systems for storage, each portion being sized to accommodate the weighting function of a corresponding one of the plurality of systems. That is, the portions may be of unequal size, depending upon the capabilities of the systems to which they are to be assigned for storage. Each portion is tagged with encoded data identifying its sequence in the data file and the system to which it is assigned for storage. Additionally, and in order to preserve privacy and protection against contamination, each portion or token is digitally signed and encrypted by known techniques. Preferably, each token also includes error correcting code, such as a form of Reed-Solomon errors-and-erasures decoder, for the previous token and its identifying information and the next token and its identifying information to aid in reconstructing tokens which may become lost in the scatter/gather operation.
- [0012] As the portions are created and tagged, an index table is created at the one system from which the file is to be stored which identifies each tagged portion and the system to which that tagged portion is assigned for storage. The table is then transmitted to each of the systems at which a tagged portion is stored for retention and use in retrieval of the data file.
- [0013] When a data file so stored is to be retrieved, an instruction at one of said plurality of computer systems to retrieve from storage a data file stored in scattered portions in a plurality of the computer systems causes responses of accessing a table stored accessibly to the one computer system which identifies a plurality of tagged portions and the identity of the computer system to which the respective tagged portion is assigned for storage. As noted above, each of the portions or tokens has been sized to accommodate a weighting function of a corresponding one of the plurality of systems. The scattered portions are then gathered from the plurality of computer systems to the one computer system, decrypted as necessary, and assembled into the

data file.

- [0014] Referring now more particularly to Figure 1, a LAN is there represented at 10 and has a plurality of computer system workstations 11 connected together there through. Each workstation has data storage capability provided by, for example, a rotating magnetic media hard disc drive (not specifically shown due to being conventionally well known). Storage capability may be provided by other types of devices, including re-writable optical disks, flash memory media, and the like. The capacity for storage data, accessibility over the LAN 10, and available rates of data transfer will be taken into account in determining a weighting function for each system. That weighting function will be used in determining the size of any portion or token to be assigned to that system for storage, should one of the systems on the LAN implement scattered file storage.
- [0015] Referring now to Figure 2, the sequence of steps which occur when a user of one workstation calls for scattered file storage are represented. A data file to be stored is divided or broken into a plurality of portions or tokens, sized for recoverability and for the weighting functions of systems having available storage capability. Each token is digitally signed for its origin and encrypted, a process here referred to as tagging. Each token is hashed with a unique machine identification and a marker denoting where in the sequence of portions it belongs. Error correcting code preferably is included, relating a token to the next previous token in the sequence and the next subsequent token in the sequence, to aid in reconstructing tokens if necessary. Should there be a number of tokens which exceed the available systems to receive them in a scatter operation, then no two contiguous tokens are stored on the same system. If deemed appropriate or necessary, tokens may be stored on multiple systems, in order to provide redundancy for safety.
- [0016] An index table is constructed on the originating system composed of all the hash codes, error correcting codes, and systems identifications for the systems to which the data file has been scattered. Once completed, the table may be compressed, digitally signed for identification, encrypted, and then distributed to each system which has received one of the portions.
- [0017] Referring now to Figure 3, the sequence of steps which occur when a user of one

of the systems calls for recovery of a stored file are represented. On instructions to retrieve a file, the index table is opened and qualified by checking the signature and, if correct, decrypting as necessary. The table is then referenced to determine the locations and sequence of the stored tokens. The tokens can then be gathered, decrypted as necessary, and the file restored. If any tokens are missing, the error correction data stored in the next preceding and following tokens are used. If a number of contiguous tokens are missing, then the error correcting information stored in the table and the next preceding and following tokens are used.

Reconstruction can be recursively repeated until restoration is complete or it is determined that the data file has become so corrupted as to be unusable.

- [0018] In the event that a signature is deemed incorrect, then a search through the connected systems is undertaken to discover a correctly signified copy of the table. The reconstruction then proceeds using that identified table, and as described above.
- [0019] Referring now to Figure 4, a diskette is there shown as being one form of computer readable media on which may be stored, accessibly to a computer system 11, instructions for performance of the processes described above and with reference to Figures 2 and 3.
- [0020] In the drawings and specifications there has been set forth a preferred embodiment of the invention and, although specific terms are used, the description thus given uses terminology in a generic and descriptive sense only and not for purposes of limitation.
